

Widget CLI Reference

Installation

Install the Widget CLI from the package index. The CLI requires a recent runtime and writes its configuration to the user config directory.

```
pip install widget-cli
```

```
widget --version
```

Commands

The CLI groups its functionality into subcommands. Each subcommand accepts its own flags; global flags are accepted before the subcommand name.

widget build

Compile the project into a deployable artifact. The build step reads the manifest in the working directory and writes output to the build folder.

```
widget build --target prod --out ./dist
```

Build options

The build subcommand accepts a small set of options:

- `--target` selects the build profile (dev or prod).
- `--out` overrides the output directory.
- `--clean` removes prior artifacts before building.

widget deploy

Push a built artifact to a named environment. Deployment is atomic and rolls back automatically if the health check fails.

```
widget deploy --env staging --artifact ./dist/app.tar
```
